

Certificate

This is to certify that

Mr./Ms. NIRAJKUMAR ITALIYA Of class
CE Sem-5 Division A2 Enrollment No 190130107041 Has
satisfactorily completed his/her term work in
ADA(3150703) Subject for the term ending in
November 2021-2022.

Date:- 23/09/2021

Government Engineering College, Gandhinagar

Computer Engineering B.E. Semester V (AY 2021-22)

SUBJECT

ANALYSIS AND DESIGN OF ALGORITHMS (3150703)

Student Details:

Enrolment No. :	190130107041
Full Name : (Surname Mid. First Name)	Italiya NirajKumar Vijaybhai
Sub-Division:	A2
Email Id:	nirajitaliya2019@gecg28.ac.in
Contact Number:	8140810073

Student Details:

Student:	
Subject Coordinator/Lab Faculty:	
HOD Signature:	

Vision and Mission

Institute (GECG):

Vision:	To be a premier engineering institution, imparting quality education for innovative solutions relevant to society and environment.
Mission:	<ul style="list-style-type: none">● To develop human potential to its fullest extent so that intellectual and innovative engineers can emerge in a wide range of professions.● To advance knowledge and educate students in engineering and other areas of scholarship that will best serve the nation and the world in future.● To produce quality engineers, entrepreneurs and leaders to meet the present and future needs of society as well as the environment.

Department (CE):

Vision:	To achieve excellence for providing value based education in Computer Engineering through innovation, teamwork and ethical practices.
Mission:	<ul style="list-style-type: none">● To produce computer science and engineering graduates according to the needs of industry, government, society and scientific community.● To develop partnership with industries, government agencies and R and D Organizations● To motivate students/graduates to be entrepreneurs.● To motivate students to participate in reputed conferences, workshops, symposiums, seminars and related technical activities

Practical 1

**Implementation and Time analysis of sorting algorithms.
Bubble sort, Selection sort, Insertion sort, Merge sort and
Quicksort.**

Bubble Sort

Algorithm:

```
begin BubbleSort(list,n)
    for pass=0, pass<n-1, pass++
        for i=0, i<=n-1-pass, i++
            if list[i] > list[i+1]
                swap(list[i], list[i+1])
            end if
        end for
    end for
    return list
end BubbleSort
```

Time Complexity:

Here there are two for loops, So time complexity is $O(n^2)$.

Space Complexity:

Here there is one array of size n, So space complexity is $O(n)$.

Recurrence Relation:

$$T(n) = T(n-1) + n$$

Similarly,

$$T(n-1) = T(n-2) + n-1$$

So on till,

$$= T(1) + (2+3+\dots+n)$$

$$= T(0) + (1+2+3+\dots+n)$$

$$= T(0) + n*(n+1)/2$$

$$= O(n^2)$$

Implementation :

```
print("Niraj Italiya 190130107041")
```

```
print("5CEA2")
```

```
def bubbleSort(arr):
```

```
    n = len(arr)
```

```
    for i in range(n-1):
```

```
        for j in range(0, n-i-1):
```

```
            if arr[j] > arr[j+1] :
```

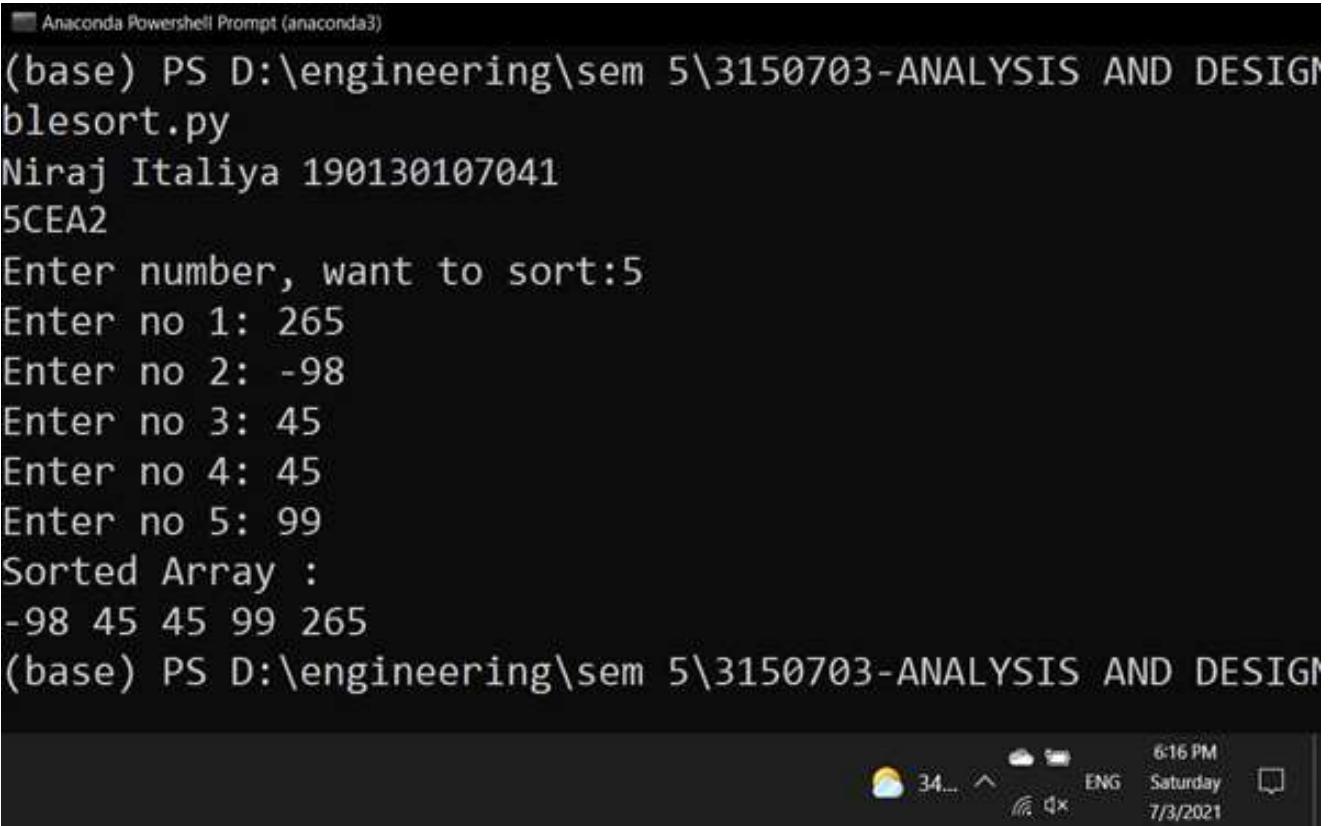

```
                arr[j], arr[j+1] = arr[j+1], arr[j]
```

```
size = int(input("Enter number, want to sort:"))
```

```
arr = []
for i in range(size):
    value = int(input("Enter no {i}: ".format(i=i+1)))
    arr.append(value)
bubbleSort(arr)
```

```
print("Sorted Array : ")
for i in range(size):
    print(arr[i], end = " ")
```

Output:

```
Anaconda Powershell Prompt (anaconda3)
(base) PS D:\engineering\sem 5\3150703-ANALYSIS AND DESIGN
blesort.py
Niraj Italiya 190130107041
5CEA2
Enter number, want to sort:5
Enter no 1: 265
Enter no 2: -98
Enter no 3: 45
Enter no 4: 45
Enter no 5: 99
Sorted Array :
-98 45 45 99 265
(base) PS D:\engineering\sem 5\3150703-ANALYSIS AND DESIGN
```

The screenshot shows a terminal window titled "Anaconda Powershell Prompt (anaconda3)". The command "blesort.py" is run, displaying student information: Niraj Italiya, ID 190130107041, and program code name 5CEA2. The user is prompted to enter numbers to sort, with 5 being input. The sorted array [-98, 45, 45, 99, 265] is then printed. The taskbar at the bottom of the screen shows system icons and the date/time: 6:16 PM Saturday 7/3/2021.

Conclusion:

- To sort a list of 'n' by bubble sort it will take $n-1$ iteration.
- After each pass the heaviest element is on the rightmost posⁿ.
- Worst case would be when array is in descending order.
- Algorithm can be improved by adding a flag to stop the inner loop if no swaps occurred.

Selection Sort

Algorithm:

```
Begin selection sort (list,n)
    for i = 1 to n - 1
        min = i
        for j = i+1 to n
            if list[j] < list[min] then
                min = j;
            end if
        end for
        if indexMin != i then
            swap list[min] and list[i]
        end if
    end for
end selection sort
```

Time Complexity:

Here there are two for loops, So time complexity is $O(n^2)$.

Space Complexity:

Here there is one array of size n, So space complexity is $O(n)$.

Recurrence Relation:

$$T(n) = T(n-1) + n$$

Similarly,

$$T(n-1) = T(n-2) + n-1$$

So on till,

$$= T(1) + (2+3+\dots+n)$$

$$= T(0) + (1+2+3+\dots+n)$$

$$= T(0) + n*(n+1)/2$$

$$= O(n^2)$$

Implementation :

```
print("Niraj Italiya 190130107041")
```

```
print("5CEA2 Practical 1")
```

```
def selectionSort(arr):
```

```
    n = len(arr)
```

```
    for i in range(n):
```

```
        min_in = i
```

```
        for j in range(i+1, n):
```

```
            if arr[min_in] > arr[j]:
```

```
                min_in = j
```

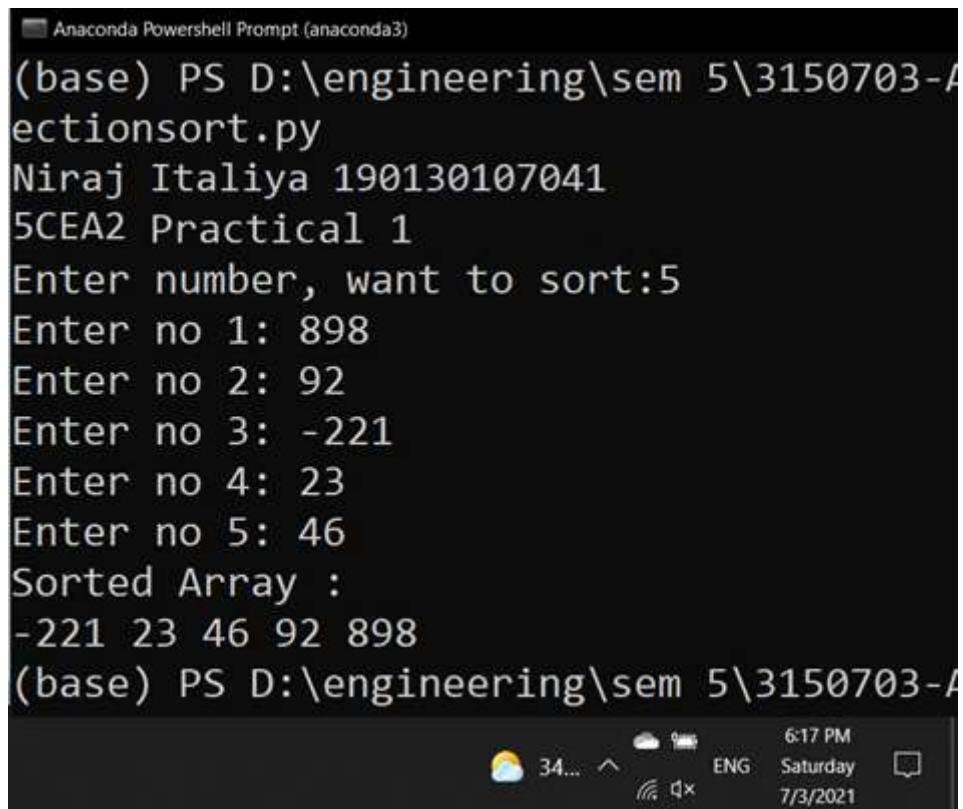

```
            arr[i], arr[min_in] = arr[min_in], arr[i]
```

```
size = int(input("Enter number, want to sort:"))

arr = []
for i in range(size):
    value = int(input("Enter no {i}: ".format(i=i+1)))
    arr.append(value)
selectionSort(arr)

print("Sorted Array : ")
for i in range(size):
    print(arr[i], end = " ")
```

Output:

The screenshot shows a terminal window titled 'Anaconda Powershell Prompt (anaconda3)'. The command '(base) PS D:\engineering\sem 5\3150703-A' is entered. The user runs the script 'selectionsort.py' which prints their details: 'Niraj Italiya 190130107041' and '5CEA2 Practical 1'. The program then prompts for the size of the array to be sorted: 'Enter number, want to sort:5'. The user enters five values: 898, 92, -221, 23, and 46. Finally, the sorted array is printed: '-221 23 46 92 898'. The bottom status bar shows system information including battery level (34%), network signal, ENG, Saturday, 6:17 PM, and 7/3/2021.

Conclusion:

- Selection sort is a combination of searching and sorting.
- After each pass the smallest element is on the leftmost posⁿ.
- Worst case would be when array is in descending order
- To sort a list of 'n' by selection sort it will take n-1 passes.
- Best case worse case avg case are all O(n²).

Insertion Sort

Algorithm:

```
Begin insertion sort (list,n)
    for j = 2 to n
        key = list[j]
        i = j-1
        while i > 0 and list[i] > key
            list[i+1] = list[i]
            i = i-1
        end while
    end for
end insertion sort
```

Time Complexity:

Here there are two for loops, So time complexity is $O(n^2)$.

Space Complexity:

Here there is one array of size n, So space complexity is $O(n)$.

Recurrence Relation:

$$T(n) = T(n-1) + n$$

Similarly,

$$T(n-1) = T(n-2) + n-1$$

So on till,

$$= T(1) + (2+3+\dots+n)$$

$$= T(0) + (1+2+3+\dots+n)$$

$$= T(0) + n*(n+1)/2$$

$$= O(n^2)$$

Implementation :

```
print("Niraj Italiya 190130107041")
```

```
print("5CEA2 Practical 1")
```

```
def insertionSort(arr):
```

```
    n = len(arr)
```

```
    for i in range(n):
```

```
        k = arr[i]
```

```
        j = i-1
```

```
        while j >= 0 and k < arr[j]:
```

```
            arr[j+1] = arr[j]
```

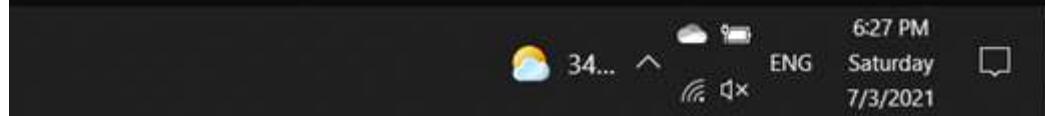

```
j = j-1  
arr[j+1] = k
```

```
size = int(input("Enter number, want to sort:"))
```

```
arr = []  
for i in range(size):  
    value = int(input("Enter no {i}: ".format(i=i+1)))  
    arr.append(value)  
insertionSort(arr)  
print("Sorted Array : ")  
for i in range(size):  
    print(arr[i], end = " ")
```

17

Conclusion:

- To sort a list of ‘n’ by insertion sort we divide it into two virtual arrays, a sorted array and an unsorted array.
- After each pass the selected element gets placed into the correct place in the sorted array.
- Worst case would be when array is in descending order.

Quick Sort

Algorithm:

```
Begin partitionFunc(left, right, pivot)
    leftPointer = left
    rightPointer = right - 1
    while True do
        while A[++leftPointer] < pivot do
            //do-nothing
        end while
        while rightPointer > 0 && A[--rightPointer]
        > pivot
            do
        end while
        if leftPointer >= rightPointer
            break
        else
            swap leftPointer,rightPointer
        end if
    end while
    swap leftPointer,right
    return leftPointer
end partitionFunc
```

Time Complexity:

Here there are two for loops, So time complexity is $O(n (\log n))$.

Space Complexity:

Here there is one array of size n, So space complexity is $O(n (\log n))$.

Recurrence Relation:

$$T(n) = T(n-1) + n$$

$$[T(n) = O(n) + T(0) + T(n-1) = O(n) + T(n-1)]$$

Similarly,

$$T(n-1) = T(n-2) + n-1$$

So on till,

$$= T(1) + (2+3+\dots+n)$$

$$= T(0) + (1+2+3+\dots+n)$$

$$= T(0) + n*(n+1)/2$$

$$= O(n^2)$$

Implementation :

```
print("Niraj Italiya 190130107041")
```

```
print("5CEA2 Practical 1")
```

```
def partition(arr, low, high):
```

```
    i = (low-1)
```

```
    pivot = arr[high]
```

```
for j in range(low, high):
    if arr[j] <= pivot:
        i = i+1
        arr[i], arr[j] = arr[j], arr[i]

    arr[i+1], arr[high] = arr[high], arr[i+1]
return (i+1)
```

```
def quickSort(arr, low, high):
    if len(arr) == 1:
        return arr
    if low < high:
        pi = partition(arr, low, high)
        quickSort(arr, low, pi-1)
        quickSort(arr, pi+1, high)
```

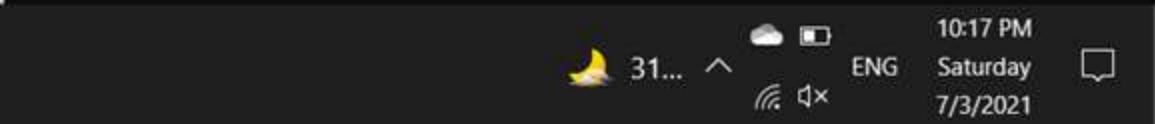

```
size = int(input("Enter number, want to sort:"))

arr = []
for i in range(size):
    value = int(input("Enter no {i}: ".format(i=i+1)))
    arr.append(value)
```

```
n = len(arr)  
quickSort(arr, 0, n-1)  
print("Sorted Array : ")  
for i in range(size):  
    print(arr[i], end = " ")
```

Output:

(base) PS D:\engineering\sem 5\3150703-ANALYSIS AND
```

Conclusion:

- To sort a list of 'n' by quicksort we select a pivot and partitioning the other elements into two sub-arrays, according to whether they are less than or greater than the pivot
- Sub arrays are sorted recursively
- Worst case would be when pivot is at the beginning pr the end , i.e the array is sorted
- Best case occurs when median element is selected as pivot

Merge Sort

Algorithm:

Begins mergeSort(arr[], l, r)

If $r > l$

 Find the middle point to divide the array into two halves:

 middle $m = l + (r-l)/2$

 Call mergeSort for first half:

 Call mergeSort(arr, l, m)

 Call mergeSort for second half:

 Call mergeSort(arr, m+1, r)

 Merge the two halves sorted in step 2 and 3:

 Call merge(arr, l, m, r)

Time Complexity:

Here there are two for loops, So time complexity is

$O(n (\log n))$.

Space Complexity:

Here there is one array of size n , So space complexity is

$O(n)$.

Space Complexity:

Here there is one array of size n, So space complexity is $O(n (\log n))$.

Recurrence Relation:

$$T(n) = 2T(n/2) + \Theta(n)$$

Similarly,

$$T(n)=2T(n/2)+n,$$

$$=4T(n/4)+2n,$$

$$=2^k T(n/2^k)+kn$$

(Where , no. of reoccurrences till $T(n/2)=T(1)$ is $\log_2(n)$ so, substituting $k= \log_2(n)$, we get)

$$=O(n \log n)$$

Implementation :

```
print("Niraj Italiya 190130107041")
```

```
print("5CEA2 Practical 1")
```

```
def merge(arr, l, m, r):

Practical 2

Implementation and Time analysis of linear and binarysearch algorithm.

Linear Search

Algorithm:

```
begin linear_search (list, value)
    for each item in the list
        if match item == value
            return the item's location
    end if
end linear_search
```

Time Complexity:

Here we are searching the entire array for every element, So time complexity is $O(n)$.

Space Complexity:

Here we are returning only the index of one element, So space complexity is $O(1)$.

Derivation :

For linear search simply iterate through the array and if the element is not present then that is the worst case ,

```
for(i=0;i<n;i++)  
{  
    If(a[i]==key)  
    {  
        printf("key found at %d",i);  
    }  
}
```

This gets executed $1+(n+1)+n+(n-1)$ times so overall we get,

$=O(n)$

Implementation :

```
print("Niraj Italiya 190130107041")  
print("5CEA2 Practical 2-Linear Search")
```

```
def LinearSearch(arr, x):  
    for i in range(len(arr)):  
  
        if arr[i] == x:  
            return i  
  
    return -1
```

```
size = int(input("How many elements you have? :"))
```

```
arr = []
```

```
for i in range(size):
```

```
    value = int(input("Enter no {i}: ".format(i=i+1)))
```

```
    arr.append(value)
```

```
x = int(input("Enter element to search :"))
```

```
result = LinearSearch(arr, x)
```

```
if result != -1:
```

```
    print("Element is found at {i}".format(i=result))
```

```
else:
```

```
    print("Element is not found.")
```

Output:

Enter element to search :23  
Element is found at index 3  
(base) PS D:\engineering\sem 5\3150703-ANALYSIS AND DES
```

Conclusion:

- To search a list of ‘n’ by linear search start from index 0 and go till n and see if you found the key element.
- Worst case would be when key element will not be present in the array.

Binary Search

Algorithm:

```
begin binary_search
    Set low = 1
    Set high = n
    while key not found
        if high < low
            EXIT: key does not present in array.
        set mid = low + ( high – low ) / 2
        if A[mid] < key
            set low = mid + 1
        if A[mid] > key
            set high = mid - 1
        if A[mid] = key
            EXIT: key found at location mid
    end while

end binary_search
```

Time Complexity:

Here we are searching the entire array for every element, So time complexity is $O(\log n)$.

Space Complexity:

Here we are returning only the index of one element, So space complexity is $O(1)$.

Reoccurrence Relation:

$$T(n) = T(n/2) + 1$$

a=1 b=2 k=0 p=0

a=b^k

$$T(n) = \Theta(n^{\log_b a} \log^{p+1} n)$$

$$= \Theta(n^{\log_2 1} \log^{0+1} n)$$

$$= \Theta(\log n)$$

Implementation :

```
print("Niraj Italiya 190130107041")
print("5CEA2 Practical 2-Linear Search")
```

```
def binarySearch(arr, low, high, x):
```

```
    if high >= low:
```

```
        mid = (high + low) // 2
```

```
        if arr[mid] == x:
```

```
            return mid
```

```

        elif arr[mid] > x:
            return binarySearch(arr, low, mid - 1, x)
        else:
            return binarySearch(arr, mid + 1, high, x)
        else:
            return -1

size = int(input("How many elements you have? :"))

arr = []
for i in range(size):
    value = int(input("Enter no {i}: ".format(i=i+1)))
    arr.append(value)
n=len(arr)

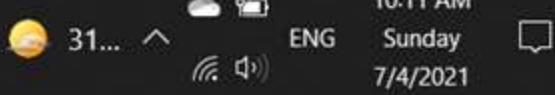

x = int(input("Enter element to search :"))
result = binarySearch(arr, 0, n-1, x)

if result != -1:
    print("Element is found at index {}".format(i=result))
else:

10:11 AM
31... ENG Sunday 7/4/2021

Conclusion:

- To search a list of ‘n’ by binary search we divide it into two parts, and based on relⁿ b/w key and mid we go to left or right sub-halves.
- After each pass the size of array reduces by half.
- Worst case would be when array is when the key element is (not in the array/in the last position relative to the search)
- Algorithm has constant complexity for best case O(1).

Practical 3

Implementation the min and max heap sort algorithm.

Max Heap

Algorithm:

```
begin maxHeap(list,n)
```

 Arr[(i-1)/2] Returns the parent node.

 Arr[(2*i)+1] Returns the left child node.

 Arr[(2*i)+2] Returns the right child node.

```
end maxHeap
```

- **getMax():** It returns the root element of Max Heap. Time Complexity of this operation is O(1).
- **extractMax():** Removes the maximum element from MaxHeap. Time Complexity of this Operation is O(Log n) as this operation needs to maintain the heap property (by calling heapify()) after removing root.
- **insert():** Inserting a new key takes O(Log n) time. We add a new key at the end of the tree. If new key is smaller than its parent, then we don't need to do anything. Otherwise, we need to traverse up to fix the violated heap property.

Time Complexity:

Here there are two for loops, So time complexity is $O(n \log n)$.

Space Complexity:

Here there is one array of size n, So space complexity is $O(1)$.

Recurrence Relation:

$$T(n) = T(n-1) + O(\log n)$$

Similarly,

$$T(n) = O(n) + n O(\log n)$$

$$= O(n \log n)$$

Implementation :

```
import sys

print("190130107041 Niraj Italiya")
print("5CEA2 Practical 3-Max Heap")

class MaxHeap:

    def __init__(self, maxsize):

        self.maxsize = maxsize
        self.size = 0
        self.Heap = [0] * (self.maxsize + 1)
        self.Heap[0] = sys.maxsize
        self.FRONT = 1
```

```

def parent(self, pos):
    return pos //2

def leftChild(self, pos):
    return 2 * pos

def rightChild(self, pos):
    return (2 * pos) + 1

def isLeaf(self, pos):
    if pos >= (self.size//2) and pos <= self.size:
        return True
    return False

def swap(self, fpos, spos):
    self.Heap[fpos], self.Heap[spos] = (self.Heap[spos],
                                         self.Heap[fpos])

def maxHeapify(self, pos):
    if not self.isLeaf(pos):
        if (self.Heap[pos] < self.Heap[self.leftChild(pos)] or

```

```
self.Heap[pos] < self.Heap[self.rightChild(pos)]:
```

```
    if (self.Heap[self.leftChild(pos)] >  
        self.Heap[self.rightChild(pos)]):  
        self.swap(pos, self.leftChild(pos))  
        self.maxHeapify(self.leftChild(pos))
```

```
    else:  
        self.swap(pos, self.rightChild(pos))  
        self.maxHeapify(self.rightChild(pos))
```

```
def insert(self, element):
```

```
    if self.size >= self.maxsize:  
        return

    PARENT : 48 LEFT CHILD : 23 RIGHT CHILD : 5
    PARENT : 56 LEFT CHILD : 12 RIGHT CHILD : 23
    PARENT : 23 LEFT CHILD : 5 RIGHT CHILD : 5
The Max val is 236
(base) PS D:\engineering\sem 5\3150703-ANALYSIS AND DESIGN OF ALGO
```

The screenshot shows a Windows taskbar at the bottom of the screen. From left to right, it includes: a yellow circular icon with a white 'C' (likely a custom icon or a specific application icon), the text '31...', a battery icon showing approximately 30% charge, a signal strength icon, an 'ENG' text, a small upward arrow, a 'Sunday' text, a '10:32 AM' timestamp, a square icon with a diagonal line, and the date '7/4/2021'.

Conclusion:

- To sort a list of max heap sort it will take n iteration.
- After each pass the heaviest element is on the rightmost posⁿ.
- Worst case would be when array is in descending order.

Min Heap

Algorithm:

```
begin minHeap(list,n)
    Arr[(i -1) / 2] returns its parent node.
    Arr[(2 * i) + 1] returns its left child node.
    Arr[(2 * i) + 2] returns its right child node.
end minheap
```

- **getMax()**: It returns the root element of Max Heap. Time Complexity of this operation is O(1).
- **extractMax()**: Removes the maximum element from MaxHeap. Time Complexity of this Operation is O(Log n) as this operation needs to maintain the heap property (by calling heapify()) after removing root.
- **insert()**: Inserting a new key takes O(Log n) time. We add a new key at the end of the tree. If new key is smaller than its parent, then we don't need to do anything. Otherwise, we need to traverse up to fix the violated heap property.

Time Complexity:

Practical 4

Implementation and Time analysis factorial program using iterative and recursive method.

Algorithm:

Using Iteration:

```
factorial(number)
    FOR value = 1 to number
        factorial = factorial * value
    END FOR
    Return factorial
end
```

Using Recursion:

```
factorial(number)
    IF number == 0 or 1
        Return 1
    Else
        Return n * factorial(number-1)
end
```

Recurrence Relation:

$$T(n) = T(n-1) + T(n-2) + \Theta(1)$$

Similarly,

$$T(n-1) = T(n-2) + n - 1$$

So on till,

$$= T(1) + (2+3+\dots+n)$$

$$= T(0) + (1+2+3+\dots+n)$$

$$= T(0) + n*(n+1)/2$$

$$= \Theta(n)$$

import time
import datetime
current_time = datetime.datetime.now()
initial = time.time()
# Python3 program to solve fractional
# Knapsack Problem
class ItemValue:
    """Item Value DataClass"""
    def __init__(self, wt, val, ind):
        self.wt = wt
        self.val = val
        self.ind = ind
        self.cost = val // wt
    def __lt__(self, other):
        return self.cost < other.cost
# Greedy Approach
class FractionalKnapSack:
    """Time Complexity O(n log n)"""
    @staticmethod
    def getMaxValue(wt, val, capacity):
        """function to get maximum value """
        iVal = []
        for i in range(len(wt)):
            iVal.append(ItemValue(wt[i], val[i], i))

```

```

iVal.sort(reverse=True)
totalValue = 0
for i in iVal:
    curWt = int(i.wt)
    curVal = int(i.val)
    if capacity - curWt >= 0:
        capacity -= curWt
        totalValue += curVal
    else:
        fraction = capacity / curWt
        totalValue += curVal * fraction
        capacity = int(capacity - (curWt * fraction))
        break
return totalValue

# Driver Code
if __name__ == "__main__":
    wt = [10, 40, 20, 30]
    val = [60, 40, 100, 120]
    capacity = 50
# Function call
    maxValue = FractionalKnapSack.getMaxValue(wt, val,
                                                capacity)
    print(current_time)
    print("Maximum value in Knapsack =", maxValue)

```

Output:

```
2021-08-09 14:26:05.564699
Maximum value in Knapsack = 240.0
PS C:\Users\Param Radadiya> 
```

What have you learned from this experiment?

(Tick ✓ the appropriate)	Learning of	Write an appropriate answer in one or two words.
✓	Theoretical Concept	Got the concepts of knapsack problem.
✓	Problem Solving	Learnt various greedy methods.
✓	Coding Style	Definitely improved.

Assignment :- ADA

Tutorial - 1

41

Q) What is an algorithm? Explain various properties of any 4190

→ Algorithm is a step-by-step procedure which defines a set of instruction to be executed in a certain order to get the desired output. Algorithms are generally created independently of underlying languages.

7. characteristics of a algorithm

unambiguous :- algorithm should be clear and unambiguous fetch of its steps and other info should be clear and must lead to only one meaning

INPUT :- An algorithm should have one or more well defined inputs

OUTPUT :- An algorithm should have one or more well defined outputs and should match the desired output

finiteness :- algorithms must terminate after a finite number of steps

feasibility :- should be feasible with available resources

Independence: An algorithm should have step-by-step dimensions which should be independent of any program code.

What do you mean by analysis of algorithms?

→ Analysis of algo is the determination of the amount of time and space resources required to execute it.

→ usually, the efficiency or running time of an algo is stated as function relating the input length to number of steps, known as time complexity or sometimes memory known as space complexity

(3) Explain various type of Algorithm with example

1) Recursive algorithm

→ problems such as the tower of Hanoi or DFS of a graph can be easily solved by using these algo.

→ It's algo that calls itself repeatedly until problem is solved.

Ex. Here is code that finds factorial using a recursive algo

fact(y)

if y is 0

return 1

return (\rightarrow fact(y-1))

(2) Divide and conquer algo.

→ in divide and conquer algorithms,

divide the algo. in two parts, the first part divide the problem in hand in to smaller subproblems of the same type, then second part the smaller problems and solved and add together to produce the problem's final solution merge sorting and quick sorting can be done with divide and conquer algo.

Ex: merge sorting ($A[0:r], i, \sigma$) if $\sigma > 1$

1) find the mid point to divide the given array in two halves:

$$\text{middle } m = (l+r)/2$$

2) call merge sorting for the first half
call merge sorting ($A[l:m]$)

3) call merge sorting for second half
call merge sorting ($A[m+1:r]$)

4) merge the halves sorted in step 2 until 3
call merge ($A[l:r], i, \sigma$)

3) Dynamic programming algo.

→ this algo solves complex algo problems by breaking them in to multiple simple subproblems and then it solve each of them once and then stores them for future use.

Ex: Fibonacci sequence

$\text{fibonacci}(n) = 0 \quad (\text{for } n=0)$

$= 0 \quad (\text{for } n=1)$

$= \text{fibonacci}(n-1) + \text{fibonacci}(n-2)$

(for $n \geq 2$)

4) Greedy algo

→ These algo are used for solving optimization problems.

→ Huffman coding and Dijkstrer algo use two prime example where the greedy algo is used.

5) Brute force algo

→ A Brute force or algo blindly iterates all possible solutions to search one or more than one solution that may solve a function

6) Sequential search

algorithm $s\text{-search}(A[0,n], x)$

$r(n) \leftarrow x$

$i \leftarrow 0$

if $i < n$ return

else return $n-1$

6) Backtracking algo

→ Backtracking algo solves sub problem and if it the problem is over that last step and starts again to find the solution to the problem

Define: subset empty set nullset power set
pair set.

(1) subset

→ A set A is subset of another set B
if all element of set A or element of
the set B

$$A \subset B$$

(2) empty set.

→ empty set is the null set having no
elements.

$$\rightarrow \emptyset$$

(3) null string

→ The empty string is the special case where
the sequence has length zero

(4) power set

→ A power set is defined as the set of
group of all subset for any given set.

(5) equal set

→ If two set have the same and equal
element it called equal set

∴ If $A = \{1, 2, 3, 4, 5\}$

$B = \{1, 3, 5, 7, 9\}$

$U = \{1, 2, 3, 4, 5, 6, 7, 8, 9, 10\}$

(i) $A \cup B = \{1, 2, 3, 4, 5, 7, 9\}$

(ii) $A \cap B = \{1, 3, 5, 7, 9\}$

(iii) $A - B = \{2, 4\}$

(iv) $A^* = \{1, 2, 3, 4, 5\}$

(v) $A^+ B =$

$\{(1,1), (1,3), (1,5), (1,7), (1,9),$
 $(2,1), (2,3), (2,5), (2,7), (2,9),$
 $(3,1), (3,3), (3,5), (3,7), (3,9),$
 $(4,1), (4,3), (4,5), (4,7), (4,9),$
 $(5,1), (5,3), (5,5), (5,7), (5,9)\}$

(8) Arranging following growth in increasing order.

$2^n, n \log n, n^2, 1/n, \log \log n, n^3, n!$

Ans - $1, \log n, n, 2^n, \log \log n, n^2, n^3, n!$

(7) Define : Time complexity and space complexity
Worst case, best case, average case

1. Time complexity:

- Time complexity is the amount of time taken by an algorithm to run.

→ Space complexity:

→ Space complexity is the amount of space taken by an algorithm to run.

→ Worst case algo.

→ In the worst case analysis we calculate the upper bound on the running time of a algo. we must know the case that causes maximum number of operations to be executed for linear search.

→ The worst case happens when the element to be searched is not present in the array.

when x is not present, the search() function compares it with all elements of arr[] one by one to define, the worst case time complexity of linear search could be $O(n)$.

→ Average case analysis

→ In average case analysis we take all possible inputs and calculate computing time for all of the inputs sum all the calculated values and divide the sum by the total number of inputs.

→ we must know the distribution of case for the linear search problem let assume that all cases are uniformly distributed so we sum all the cases and divide the sum by $(n+1)$

→ Average case time

$$\sum_{i=1}^{n+1} O(i) = \frac{O((n+1) * (n+1)/2)}{(n+1)} = O(n)$$

→ Best case analysis

→ In Best case Analysis we calculate the lower bound on the running time of an algorithm we must know the case that cases when x is present is first position.

→ so time complexity is O(1)

v) what are asymptotic notations.

→ asymptotic notations are mathematical ways to represent the time complexity of algorithm for asymptotic analysis

(a) Define:- Big Oh, Big Omega, Big Theta

(1) O Notation:

→ The O notation bounds function from above and below so it defines exact asymptotic behaviour.

$$c_1 g(n) \leq f(n) \leq c_2 g(n)$$

for all $n \geq n_0$

(2) Big O notation:

→ The Big O notation defined on upper bound on algo it bounds at most only from above.

$$f(n) \leq c_1 g(n) \text{ for all } n \geq n_0$$

(3) Ω notation:

→ Ω notation provides an asymptotic lower bound.

→ It is useful when we have lower bound on time complexity of an algorithm.

$$c_1 g(n) \leq f(n) \text{ for all } n \geq n_0$$

TM + 00410 :- 2

(1) analyse following sorting method in best & worst case.

i) selection sort

→ also

```
for i ← 1 to n-1 do
    min s ← i;
    min x ← A[i]
    for j ← i+1 to do
        If A[j] < min x then
            min x ← A[j]
            A[min r] ← A[j]
    A[i] ← min x.
```

→ Best case (ascending order)

Ex:- 0 1 2 3 4 5
 10 20 30 40 50 60

$$\min = 10 \quad \frac{n(n-1)}{2} = O(n^2)$$

→ Worst case (descending order)

Ex: $O(n^2)$

→ Average: $O(n^2)$

ii) bubble sort :-

→ code:-

```
for (i=0; i<n-1; i++)
    { for (j=0; j<n; j++)
        {
            if (A[j] > A[j+1])
                {
```

$\text{temp} = A[j]$

$A[j] = A[j+1];$

$A[j+1] = \text{temp};$

↓

↓

↓

→ Best case :- Elements are already sorted

0	1	2	3	4
5	6	8	15	16

PASSES $n-1$ COMPARISONS MAX

THAT IS OF

COMPARISON $(n-1)(n)$

$$n^2 - 2n + 1 = O(n^2)$$

→ Worst Elements are already sorted

also $O(n^2)$

→ Average case $(n-1)(n) = O(n^2)$

(ii) Insertion sort

Code :-

for (int i=0; i<n; i++)

{ temp = A[i];

i = i-1;

while (i>=0 && A[i] > temp)

A[i+1] = A[i];

i--;

↓

$A[i+1] = \text{temp}$

↓

\rightarrow Best case (ARRY sorted)

Total no. of comparisons

$$\therefore 1+3+n+5$$

$$\therefore 1+2+3+4+(n-1)$$

$$\therefore n(n-1) - N^2 - N$$

worst case : n^2

Analyse case:-

$O(n^2)$

(iv) Quick sort

{ if ($i < h$)

$i = \text{partition}(i, h);$

 quick sort ($i, i - 1$);

 quick sort ($i + 1, h$);

y
y

→ Best case

$n = 7$

Time complexity of entire recursion tree

= No of levels * time taken for one level.

$$\frac{n}{2^k} = 1$$

$$n = 2^k$$

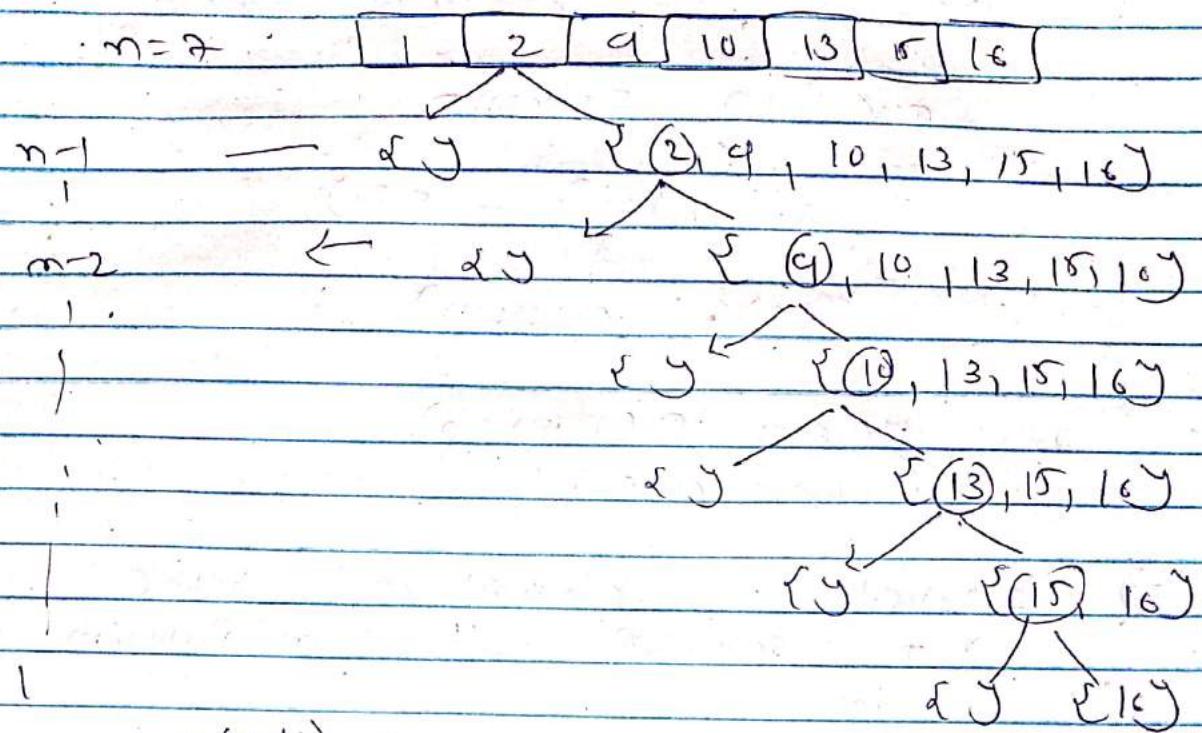

$$\log n = k \log 2$$

$$K = \frac{n \cdot \log n}{2}$$

Best case:-

$O(n \cdot \log n)$

Worst Case:-

$$= \frac{n(n+1)}{2} \rightarrow$$

$$= \frac{n^2+n}{2} \\ = O(n^2)$$

(v) Heap sort

ii) max heapify

v) build max heap

3) heap sort

Q) time complexity of max heapify

Q) time taken to fix up the relationship among elements

$A[i] \rightarrow A[\text{left}[i]], A[\text{right}[i]]$

$n = \text{no of nodes}$

any subtree of that tree in n nodes.

4

max $\frac{n}{3}$ elements

$$T(n) = T\left(\frac{2n}{3}\right) + \Theta(1)$$

$$T(n) = \Theta(n \log n)$$

2) Height $\cdot \Theta(n \log n)$
(worst case)

2) I illustrated the operation of bubble
sort selection sort in following
ways.
Bubble sort

D [31, 41, 54, 26, 41, 45, 101, 49, 78]

→ Analyze sequential search and binary search
in best and worst case

→ linear search ($A[n]$, item, loc)

Begin

for $i = 0$ to $(n-1)$ by 1 do

if $(A[i]) = \text{item}$) then

set $\text{loc} = i$

End if

end if

End for

set $\text{loc} = -1$

End

Best case

→ The element being searched may
be found at first position

→ In this case, the search terminates
in success with just one comparison

→ Thus in best case, linear search algorithm
takes $O(1)$ operations.

Worst case:-

→ The element being searched may be
present at the last position or not
present at all in the array

→ In the form we the search terminates
in success with n comparisons

In the later case the search terminates in failing with n compares.

Thus in worst case linear time O(n) operation

→ Thus:

Time:- Complexity of linear search algorithm is O(n)

Binary search A150.

Begin

set beg = 0

set end = n - 1

set mid = (beg + end) / 2

while ((beg < end) and (a[mid] ≠ item)) do

if (item < a[mid]) then

set end = mid - 1

else

set beg = mid + 1

end if

set mid = (beg + end) / 2

end while

if (beg > end) then

set loc = -1

else

set loc = mid

end if

End

→ Analysis

→ In each iteration we in each recursive call, the search get narrowed to half if the key is not for n element in the array there are about iterations recursive calls.

thus - we - have

→ Time complexity of binary search
 $O(n \log n)$

(i) compare iterative and recursive calls to find out fibonacci series

→ Iterative

def factorial (number):

product = 1

for i in range (number)

product = product * (i+1)

return product

→ Recursion [0, 1, 2]

i	product * (i+1)	product
0	1 * (0+1)	1
1	1 * (1+1)	2
2	2 * (2+1)	6

recursive

```
def factorial (numbers):  
    if numbers >= 1:  
        return 1  
    else:  
        return numbers * factorial(numbers)
```

$$\text{factorial}(3) = 6$$

↓

$$3 * \text{factorial}(2)$$

↓

$$2 * \text{factorial}(1)$$

~~~~~

↓

- (5) what do you mean by amortized analysis?

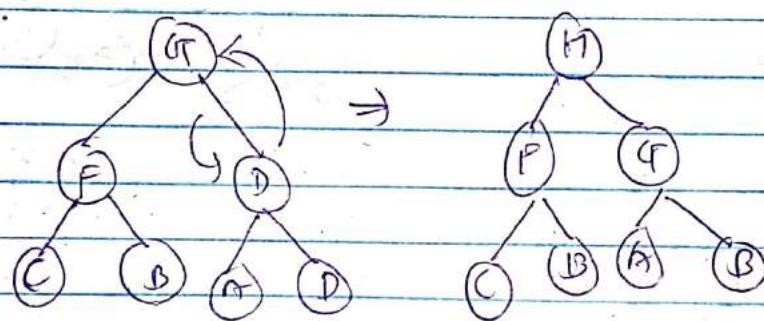

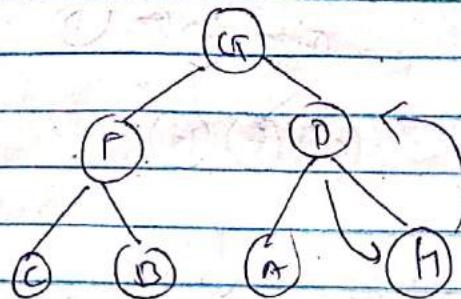

→ Amortized analysis is worst case analysis of a sequence of operations to obtain a tighter bound on the overall or average cost per operation in the sequence than is obtained by separable anything each operation in the sequence.

- (6) create min heap and max heap for following list

## Tutorial:-3

① Define:-

Ques. ① feasible solution

A solution (set of value for the decision variable) for which all the constraint in the solver model are satisfied is called a feasible solution.

② optimal solution

→ An optimal solution is feasible solution where the objective function reaches its maximum value.

③ Explain characteristic of greedy method with suitable example.

Ans. greedy (Din)

solution  $\rightarrow \emptyset$

for  $i \leftarrow 1$  to  $n$  do

{

$s \leftarrow \text{select } (D) \text{ i-th section of solution}$

if  $C(\text{feasible} (s \cup s_i))$  then

$s \cup s_i \leftarrow \text{union} (s \cup s_i, s_i)$

}

return solution

① first we select some solution from input domain

(3) from the set of feasible solution particular solution that satisfies all the necessary conditions of the objective function such a solution is called optimal solution

(3) Define:-

(1) spanning tree:-

- A spanning tree of a graph is a subgraph which is surely a tree and contains all the vertices of a connected no circuit.

(2) minimum spanning tree

→ A minimum spanning tree of a weighted connected graph is a spanning tree with minimum or smallest weight.

(3) connected graph:-

A graph in which we can visit from any one vertex to any other vertex. It called as a connected graph

(a) fully connected graph:-

→ It is a connected graph where every edge connects each pair of vertices.

### ⑤ Dense graph:-

Dense Graph is graph in which the number of edges is close to the maximum number of edges.

### ⑥ Sparse graph:-

It is a graph in which the number of edges is close to the minimum number of edges. Sparse graph can be disconnected graph.

### ⑦ Explain Prim's algo & Kruskal's algo Also write a comparison of both.

#### Pr ① Prim's algo.

→ Prim's algo: used to find the minimum spanning tree from a graph.

Step 1:- Select a starting vertex.

Step 2:- Repeat step 3. and until there are no edges.

Step 3:- select and edge or connect  
the tree root and fringe  
vertex that has minimum  
weight.

Step 4:- add the selected edge and  
the vertex to the minimum  
spanning tree.  
(End loop)

Step 5:- Exit.

## ② Kruskal's algorithm

→ Kruskal's algorithm is used to find  
the minimum spanning tree for a  
connected weight graph

→ Step 1:- Create a forest in such way  
that each graph is a complete  
tree.

→ Step 2:- Create a priority queue of type  
connect all the edges of the  
graph

- Step 3:- repeat step-1 and 2 which  
is not empty

→ Step 4:- remove and edge from

to the forest.

else

Discard the edge.

Step 6:- End

Frim's algorithm

Kruskal's algorithm

→ It starts to build the minimum spanning tree from any vertex in the graph.

It starts to build the minimum spanning tree from the vertex carrying minimum cost in the graph.

→ Prim's algorithm runs faster in dense graphs.

Kruskal's algorithm runs faster in sparse graph

→ Prim's algorithm uses list data structure.

Kruskal's algorithm uses heap data structure.

(S) Given an undirected graph as follows:-

$$v_1 \cdot v_2 = 5$$

$$v_2 \cdot v_3 = 3$$

$$v_3 \cdot v_4 = 2 \quad v_6 \cdot v_4 = 2$$

$$v_1 \cdot v_7 = 6$$

$$v_2 \cdot v_5 = 2$$

$$v_5 \cdot v_6 = 6 \quad v_8 \cdot v_6 = 4$$

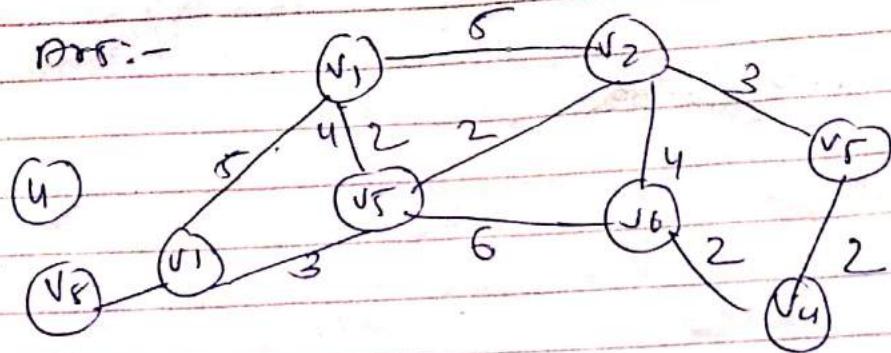

$$v_1 \cdot v_5 = 4$$

$$v_2 \cdot v_6 = 4$$

$$v_5 \cdot v_7 = 3 \quad v_7 \cdot v_8 = 5$$

Find MST using Prim's & Kruskal's algorithm.

Ans:-

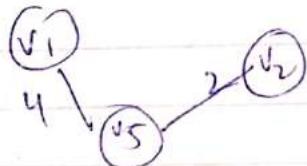

### ① Prim's algorithm:-

Step 1:-

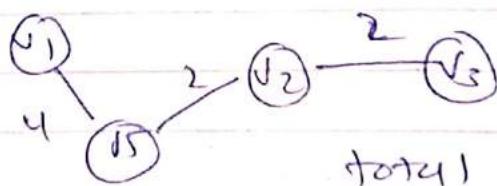

total weight = 0

Step 2:-

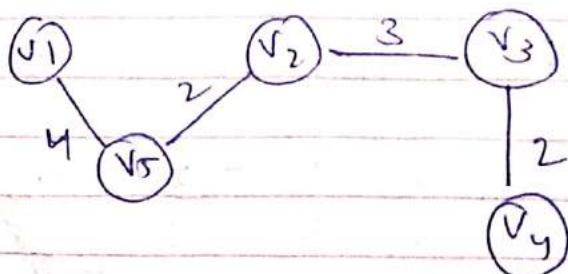

total weight = 4

Step 3:-

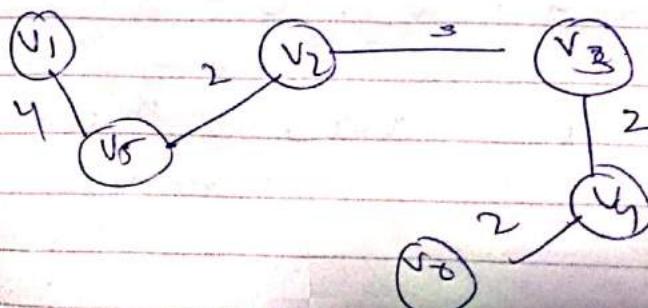

total weight = 6

Step 4:-

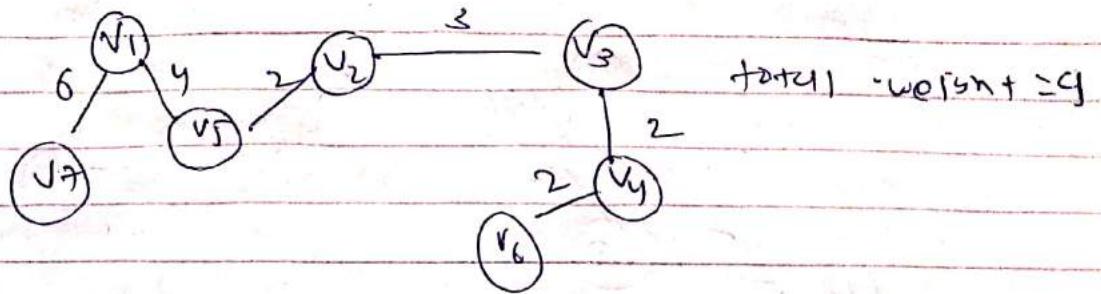

total weight = 9

Step 5:-

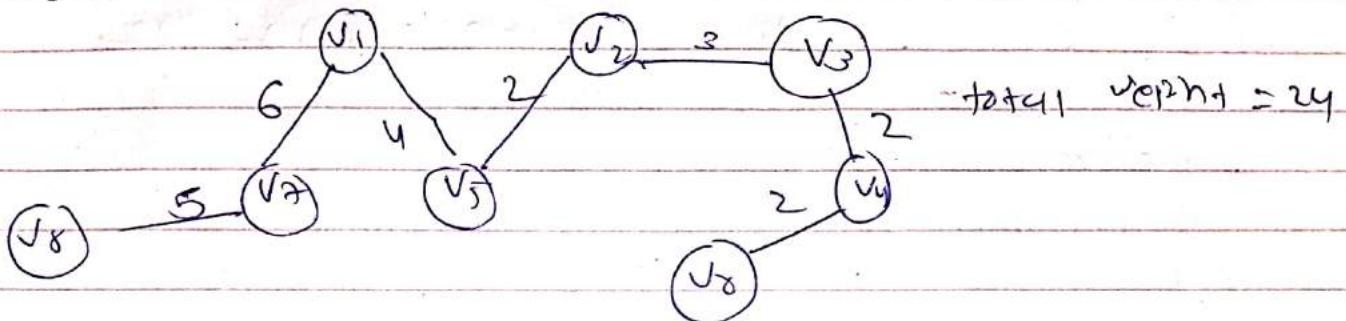

total weight = 13

Step 6:-

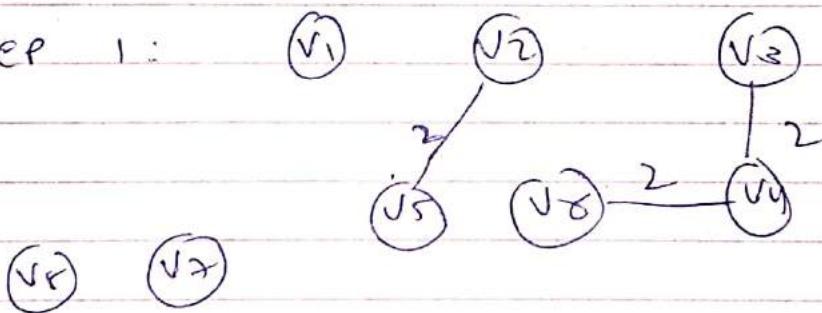

Step 7:-

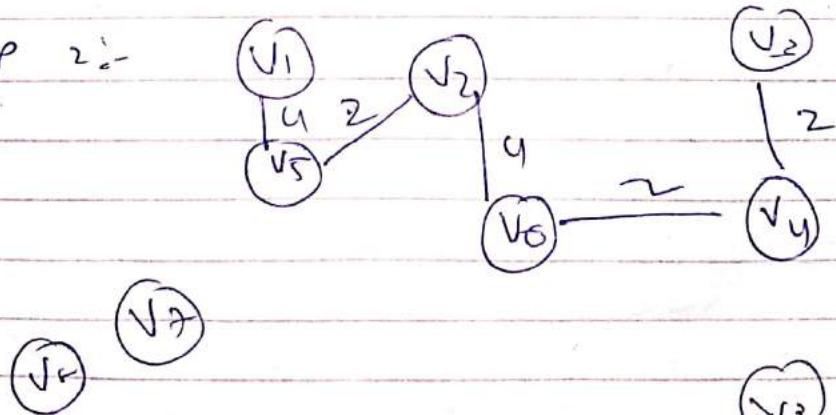

② Krosrusal's algorithm:-

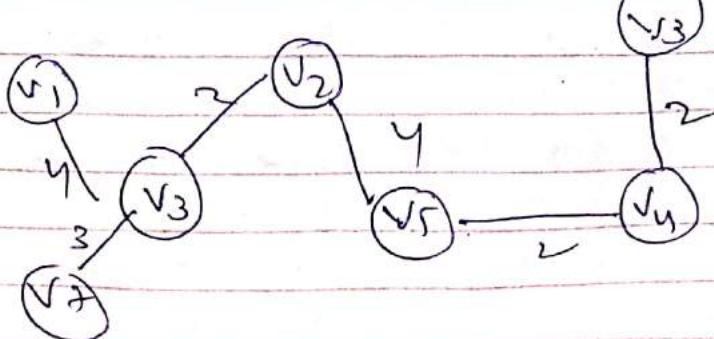

Step 1:-

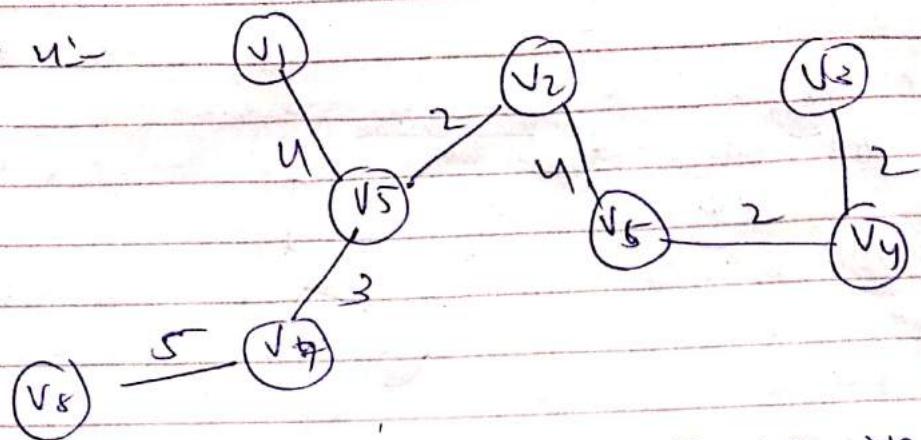

Step 2:-

Step 3:-

Step u:-

total run length = 22

~~Hot topic~~

190130107041

- \* Solve given binary knapsack problem using greedy method to get optimal profit.

$$1) N=3, w=6 \quad w(i) = (2, 3, 3) \quad v(i) = (1, 2, 4)$$

$$2) N=5, w=20 \quad w(i) = (9, 3, 5, 7, 2) \quad v(i) = (15, 14, 6, 20, 1)$$

Ans.

Select object with maximum  $v/w$  ratio

| $v/w$ | $x_1$ | $x_2$ | $x_3$ |
|-------|-------|-------|-------|
| 0.5   | 0.7   | 0.3   |       |

| Selected object | profit                     | weight                  | $v/w$ | Remaining weight |
|-----------------|----------------------------|-------------------------|-------|------------------|
| $x_1$           | 1                          | 2                       | 0.5   | 6-2 = 4          |
| $x_2$           | 2                          | 3                       | 0.7   | 4-3 = 1          |
| $x_3$           | $4 \times \frac{1}{2} = 2$ | $3 + \frac{1}{2} = 3.5$ | 1.3   | 1-1 = 0          |

Hence solution is

$$(x_1, x_2, x_3/2) \text{ with}$$

Total profit = 5

$$2) N=5, w=20$$

$$w(i) = (9, 3, 5, 7, 2)$$

$$v(i) = (15, 14, 6, 20, 10)$$

| object | 1  | 2  | 3 | 4  | 5  |
|--------|----|----|---|----|----|
| v      | 10 | 14 | 6 | 20 | 30 |
| w      | 9  | 3  | 5 | 7  | 2  |

| selected object | profit | weight | remaining weight |
|-----------------|--------|--------|------------------|
| $x_5$           | 10     | 2      | $20 - 2 = 18$    |
| $x_4$           | 20     | 7      | $18 - 7 = 11$    |
| $x_3$           | 6      | 5      | $11 - 5 = 6$     |
| $x_2$           | 14     | 3      | $6 - 3 = 3$      |

$$\text{total profit} = 50$$

$$\text{total weight} = 17$$

(2) solve the given fractional knapsack problem to get optimal profit

$$n=5 \quad w=35$$

$$w(i) = (10, 14, 12, 17, 15)$$

$$v(i) = (20, 35, 25, 40, 30)$$

Ans: Step 1: find the ratio of value and weight.

| item | weight | Profit | $p = v/w$ |
|------|--------|--------|-----------|
| 1    | 10     | 20     | 2         |
| 2    | 14     | 35     | 2.5       |
| 3    | 12     | 25     | 2.1       |
| 4    | 7      | 40     | 5.7       |
| 5    | 15     | 30     | 2         |

step 2: Arranging in order of desirability

| item | weight | profit | $P = \frac{v}{w}$ |
|------|--------|--------|-------------------|
| 4    | 7      | 40     | 5.7               |
| 2    | 14     | 35     | 2.5               |
| 3    | 12     | 25     | 2.1               |
| 1    | 10     | 20     | 2                 |
| 5    | 15     | 30     | 2                 |

(4) compare greedy and dynamic programming

| <u>one</u>                                                                           | greedy method                                                                                                                          | dynamic method                                                     |
|--------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------|
| → in greedy method sometimes time it no such guarantee of getting optimal solution.  | it is stated that dynamic programming will generate an optimal solution for it generally consider all possible as per choose the best. | in recursive deductible for mymion increase its memoed complexity. |
| → It is more efficient in term memory as it never look back or reuse previous choice |                                                                                                                                        |                                                                    |

→ A greedy method follows the problems solving heuristic of my first choosing the locally optimal choice at each stage.

In dynamic programming it is an algorithm technique which is usually based on a record for each part used some previously calculated states.

(5) Explain the term principle of optimality.

Ans The principle of optimality is the basic principle of dynamic programming.

→ which was developed by Richard Bellman that an optimal path has the property that whatever the initial condition and control variable over some initial period the control choose must be optimal for the remaining problem with the state resulting from the only decision taken to be the initial condition.

190130107041

Tutorial - 5

190130107041

Q.1 To calculate minimum number of coins where denominations are

$$d_1=1, d_2=2, d_3=5, d_4=7$$

| $i \setminus j$ | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
|-----------------|---|---|---|---|---|---|---|---|---|---|----|----|----|
| $d_1=1$         | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 |
| $d_2=2$         | 0 | 1 | 1 | 2 | 2 | 3 | 3 | 4 | 4 | 5 | 5  | 6  | 6  |
| $d_3=5$         | 0 | 1 | 1 | 2 | 2 | 1 | 2 | 2 | 3 | 4 | 4  | 5  | 5  |
| $d_4=7$         | 0 | 1 | 1 | 2 | 2 | 1 | 2 | 1 | 3 | 2 | 3  | 3  | 2  |

→ There are 2 minimum coins required to make a change

→ Now for finding ways to make change use.

| $i \setminus j$ | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9  | 10 | 11 | 12 |
|-----------------|---|---|---|---|---|---|---|---|---|----|----|----|----|
| $d_1=1$         | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1  | 1  | 1  | 1  |
| $d_2=2$         | 1 | 1 | 2 | 2 | 2 | 3 | 4 | 4 | 5 | 5  | 6  | 6  | 7  |
| $d_3=5$         | 1 | 1 | 2 | 2 | 3 | 4 | 5 | 6 | 7 | 8  | 10 | 11 | 13 |
| $d_4=7$         | 1 | 1 | 2 | 2 | 3 | 4 | 5 | 7 | 8 | 10 | 12 | 14 | 17 |

→ There are 17 ways to set change of 12 by these varied coins.

Q.2 Hence we have given that

$$P^0 = \begin{matrix} & \begin{matrix} 1 & 2 & 3 & 4 & 5 \end{matrix} \\ \begin{matrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{matrix} & \left[ \begin{matrix} 0 & 1 & \varnothing & \varnothing & \varnothing \\ \varnothing & 0 & \varnothing & 2 & 4 \\ \varnothing & \varnothing & 0 & 5 & 3 \\ \varnothing & \varnothing & \varnothing & 0 & \varnothing \\ \varnothing & \varnothing & \varnothing & \varnothing & 0 \end{matrix} \right] \end{matrix}$$

from these we will find  $P^1$  to  $P^3$

$$P^1 = \begin{matrix} & \begin{matrix} 1 & 2 & 3 & 4 & 5 \end{matrix} \\ \begin{matrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{matrix} & \left[ \begin{matrix} 0 & 1 & \varnothing & \varnothing & \varnothing \\ \varnothing & 0 & \varnothing & 2 & 4 \\ \varnothing & \varnothing & 0 & 5 & 3 \\ \varnothing & \varnothing & \varnothing & 0 & \varnothing \\ 2 & 3 & \varnothing & \varnothing & 0 \end{matrix} \right] \end{matrix}$$

$$P^2 = \begin{matrix} & \begin{matrix} 1 & 2 & 3 & 4 & 5 \end{matrix} \\ \begin{matrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{matrix} & \left[ \begin{matrix} 0 & 1 & \varnothing & 3 & 5 \\ \varnothing & 0 & \varnothing & 2 & 4 \\ \varnothing & \varnothing & 0 & 5 & 3 \\ \varnothing & \varnothing & \varnothing & 0 & \varnothing \\ 2 & 3 & \varnothing & 5 & 0 \end{matrix} \right] \end{matrix}$$

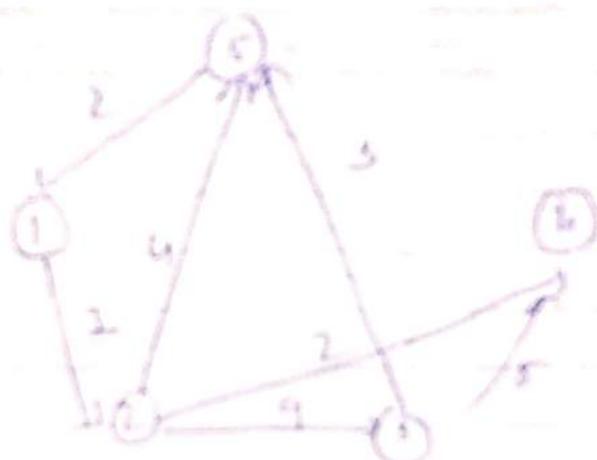

$$P^3 = \begin{matrix} & \begin{matrix} 1 & 2 & 3 & 4 & 5 \end{matrix} \\ \begin{matrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{matrix} & \left[ \begin{matrix} 0 & 1 & \varnothing & 3 & 5 \\ \varnothing & 0 & \varnothing & 2 & 4 \\ \varnothing & \varnothing & 0 & 5 & 3 \\ \varnothing & \varnothing & \varnothing & 6 & 2 \\ 1 & 3 & \varnothing & 3 & 0 \end{matrix} \right] \end{matrix}$$

$$P^4 = \begin{matrix} & \begin{matrix} 1 & 2 & 3 & 4 & 5 \end{matrix} \\ \begin{matrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{matrix} & \left[ \begin{matrix} 0 & 1 & \varnothing & 3 & 5 \\ \varnothing & 0 & \varnothing & 2 & 4 \\ \varnothing & \varnothing & 0 & 5 & 3 \\ \varnothing & \varnothing & \varnothing & 0 & \varnothing \\ 2 & 3 & \varnothing & 5 & 0 \end{matrix} \right] \end{matrix}$$

TUTORIAL - 6

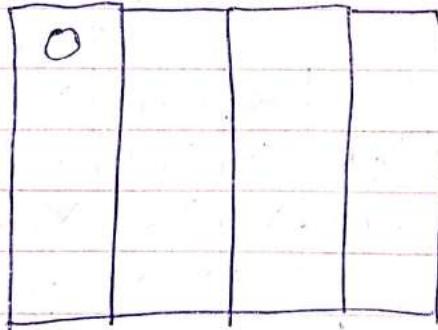

190130107041

## 1) Define backtracking

→ BACKTRACKING can be defined as a general algorithmic technique that consider searching every possible combination in order to solve a computational problem.

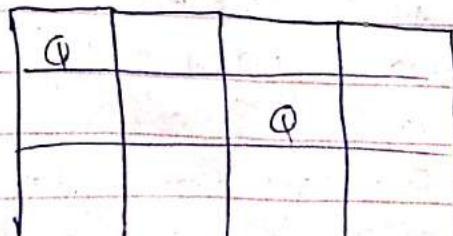

## 2) Solve n queen problem using backtracking

→ Now we start with empty chess board  
→ place queen 1 in the first possible position of it's row on 1<sup>st</sup> column.

→ then place queen 2 after trying unsuccessful place (1,2), (2,1), (2,2), & (2,3)

i.e. 2<sup>nd</sup> row and 3<sup>rd</sup> column

1)

|   |  |  |  |   |
|---|--|--|--|---|
| Q |  |  |  | Q |
|   |  |  |  |   |
|   |  |  |  |   |
|   |  |  |  |   |

→ This is the dead end because a 3rd queen can not be placed in next column as there is no acceptable position for queen 3. Hence, also backtracking and the placed the 2nd queen at (2,4) position.

|   |  |  |   |
|---|--|--|---|
| Q |  |  | Q |
|   |  |  |   |
|   |  |  |   |

The place 3rd queen at (3,2) but if again another dead end as next queen can not be placed at permissible position

→ Hence we need backtrack till the way up to queen until move it to.

|   |  |  |  |  |  |  |  |  |  |  |  |   |
|---|--|--|--|--|--|--|--|--|--|--|--|---|
| Q |  |  |  |  |  |  |  |  |  |  |  | C |
|   |  |  |  |  |  |  |  |  |  |  |  |   |
|   |  |  |  |  |  |  |  |  |  |  |  |   |
|   |  |  |  |  |  |  |  |  |  |  |  |   |
|   |  |  |  |  |  |  |  |  |  |  |  |   |

This solution is obtained (3,4,1,2)  
in rowise manner

③ Explain rabin karp method for string matching and also give the algorithm

-1 The rabin karp method is based on hashing technique. This also assumes each character to be a digit in radixed notation. It makes use of equivalence of two number modulo a third number. Let  $p \in \{1-m\}$  be a pattern then denotes its decimal value true  $d=10$  for decimal numbers  $d=2$  for binary numbers.

similary

Let  $i [0-n]$  be a text then it denotes the decimal value of the substring  $T[i:i+s]$  for  $s=0; i; n=m$

The method follows following steps

- 1) Compute  $r$  in  $O(m)$  time
- 2) Compute all value in total of  $O(n)$  time.
- 3) find all valid shift in form of  $O(p)$  time.

for example:- To compute pattern

$P[1-m] = 41603$  we have  $m=5 \geq 10$   
then

$$P = P[m] + 10[P[m-1]] + 10^2[P[m-2]] + \dots + 10^{n-1}[1]$$

we can then compute  $\rightarrow$  form  $T[s-m]$   
 in  $O(m)$  time then remaining  $T[i]$   
 can be computed in  $O(n-m)$  time  
 w.r.t.

$$T_{st+1} = d [T_s - \dots - d^{m-1} T[s+m] + T[s+m+1]]$$

where  $d=10$

Algorithm - Rabin Karp  $[T[1-n], P[1-m], q]$

1) problem description this algo is  
 1) for matching the pattern with  
 Rabin-Karp method

$$h \leftarrow \text{pow}(d, m-1) \bmod q \leftarrow$$

$$P \leftarrow 0$$

$$to \leftarrow 0$$

for ( $i \leftarrow 1$  to  $n$ )

$$\left. \begin{aligned} P &\leftarrow (dp + P[i]) \bmod q \\ to &\leftarrow (d * to + T[i]) \bmod q \end{aligned} \right\} O(n)$$

for ( $s \leftarrow 0$  to  $n-m$ )

{ if ( $P = T[s]$ ) then }

{

if ( $q(P) = T[s+m]$ ) then

write (pattern found with shift)

if ( $s(n-m)$ )

$$t_{st+1} \leftarrow (t_{st} - T[T+1]) \cdot h + T[s+m+1]$$

(n) Explain finite automata for string matching

- finite automata is a very effective tool. It is used in string matching algorithm.
- matching the pattern in this manner makes the process of string matching very efficient.
- In this method each character of the text is matched exactly once.
- Hence  $O(n)$  time is required for examining the text character by character.
- But in this algorithm a large amount of time is needed to build finite automata.
- Before learning the actual string matching algorithm let us go through some basic concepts of finite automata.
- Definition of finite automata:
- A finite automaton is a collection of states.

- ①  $Q$  is a finite set of states.
- ②  $q_0 \leftarrow q$  is a start state.
- ③  $q_E \leftarrow q$  is an accept state or
- ④  $\Sigma$  is a finite input set.
- s.t. it is a mapping function  $Q \times \Sigma \rightarrow Q$ .

for example

| start | q  | b  |
|-------|----|----|
| 20    | 2F | 20 |
| 2F    | 10 | 2C |

transition

table

→ Here 'q0' is start state and '2F' is a final state. The above design finite automata for accepting a language which consists of odd number of 'a' and even number of 'b'.

(S) for string pattern working

$$q = 11$$

pattern  $\boxed{2} \boxed{0}$

text:

$3 \boxed{1} \boxed{0} \boxed{1} \boxed{5} \boxed{9} \boxed{2} \boxed{0} \boxed{3} \boxed{5} \boxed{8} \boxed{9} \boxed{7} \boxed{9}$

$$\text{the } 20 \bmod 11 = 4$$

we will now obtain mod 11 value for each text.

Step:- ]

$3 \boxed{1} \boxed{0} \boxed{1} \boxed{5} \boxed{9} \boxed{2} \boxed{0} \boxed{3} \boxed{5} \boxed{8} \boxed{9} \boxed{7}$

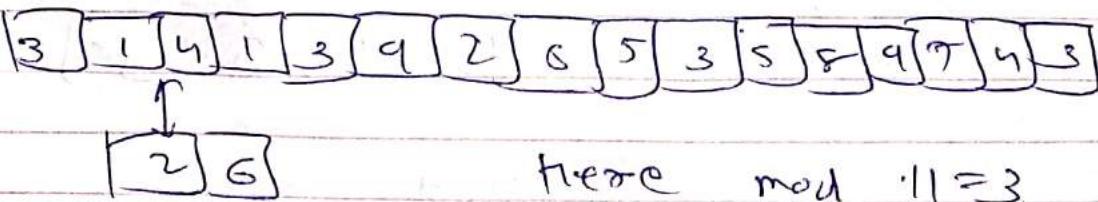

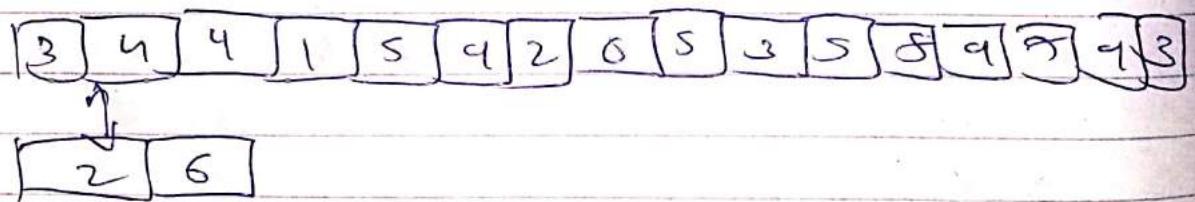

$\downarrow \quad \downarrow \quad \downarrow$

$\boxed{a} \boxed{2} \boxed{5} \boxed{4} \boxed{9} \boxed{4} \boxed{10} \boxed{9} \boxed{2} \boxed{3} \boxed{1} \boxed{9} \boxed{2} \boxed{3}$

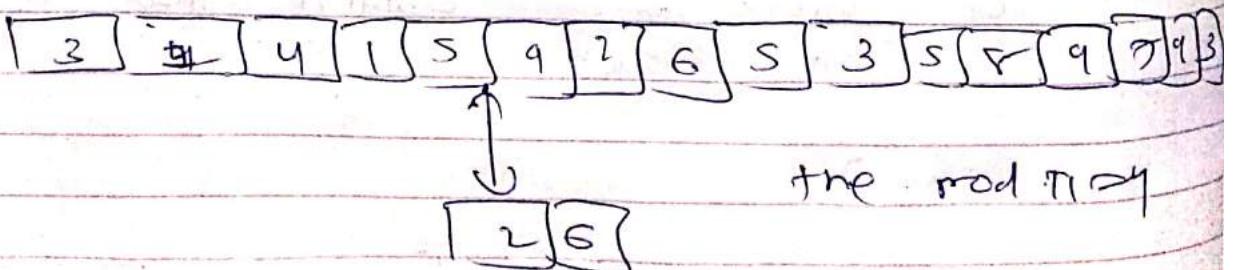

for  $m=2$  consider  $t_5 = 26$  then  
we can compute  $t_{5+1}$  as follows  
 $t_{5+1} \rightarrow (t_5 - \text{digit}) \text{ old high order}$   
digit new (with order digit)  
 $= 10(26 - 10 \times 2) + 5$   
 $= 10(26 - 20) + 5$   
 $= 60 + 5$   
 $\boxed{t_{5+1} = 65}$

→ this we can obtain every successive bit test.

→ according to Rabin-Karp method we start matching the pattern test from beginning itself

here  $\text{mod } 11 = 3$   
hence move to next

the mod 11 = 4

3 4 5 1 5 9 2 6 5 5 8 9 7 9 3

↓  
2 6

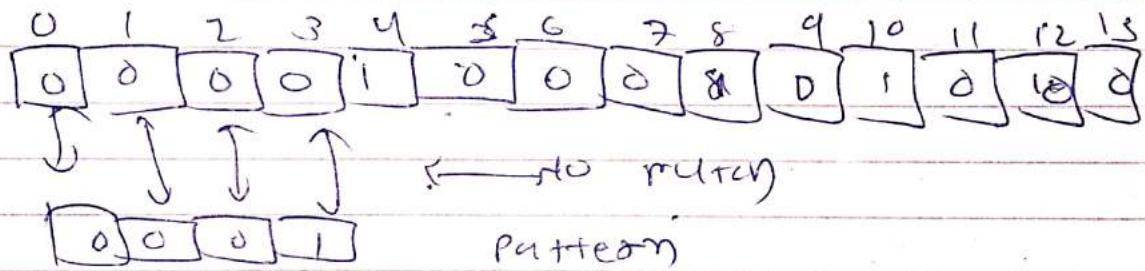

the mod is 4

and pattern is also matching  
against hence

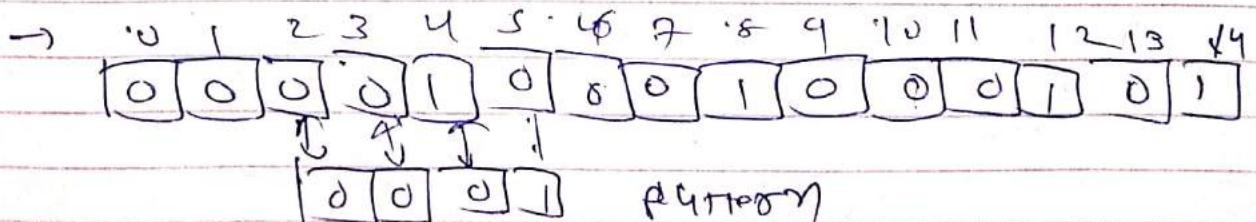

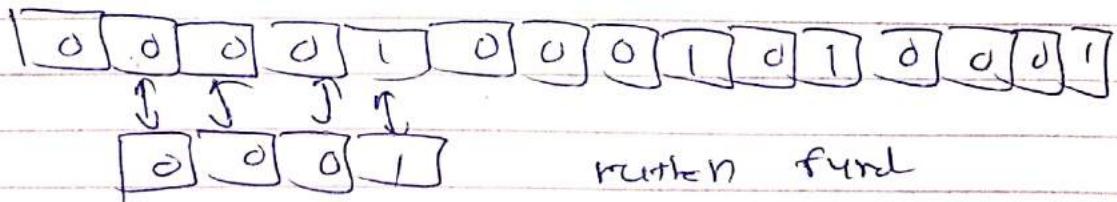

we desire that at 7th position  
we find pattern matching

- (6) show the comparisons the creative  
strings matched makes for the  
pattern  $P = 0001$  in the text  $T = 00001$   
e. 1000, 1010001

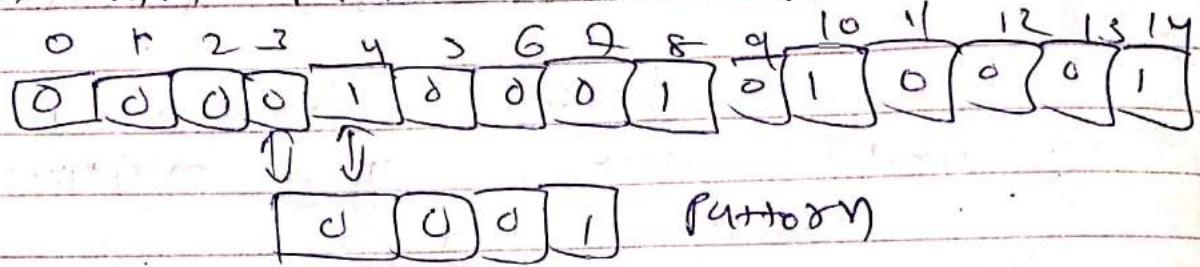

→ Let

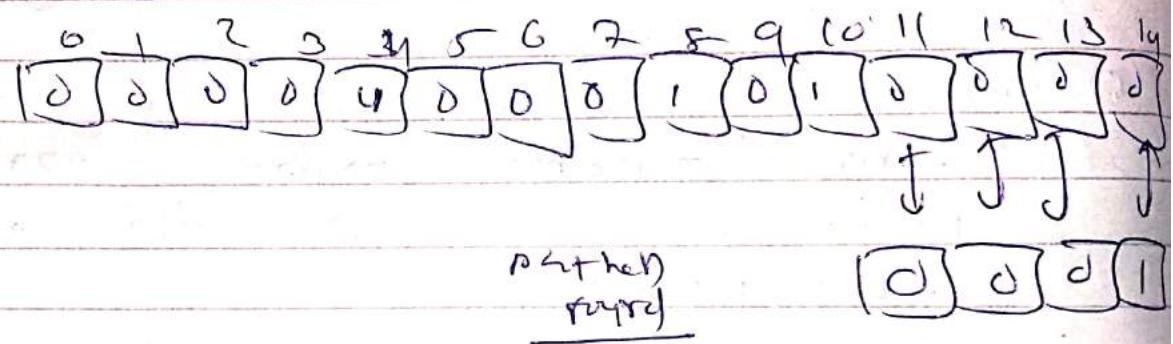

→ shift to right by one position

→ shift pattern right by one position

→ symmetrically

pattern  
repl
